Do Now!

What happens if you mis-apply functions to the wrong kinds of values? For instance, what if you give the `caml` constructor a string? What if you send a number into each version of `good?` above?

Ans:

Basically we get an error saying that the **typecheck failed**, particularly because it was a **number vs. string** in the sub-class named **caml**. The argument for the constructor of `caml` is expecting a numerical value and nothing else.

If we were to send a number into each version of **good?** (**test#** for my program), we will see again that the **typecheck failed** again, this time is a **boolean vs. number** in the boolean function called **good?** (**test#** in my program). Similarly, the boolean function is expecting either a true or false value and nothing else.
